Under the Bayesian framework, but the integration will be:

- Complex and highly dimensional (in parameters)
- On sparse binary data

but complex parametrizations introduce pathologies that prevent MCMC methods to achieve ergodicity [7, 8, 18, 19, 3], i.e. reach stationarity, convergence, and good mixing [16].

Computational implementation (cont.)

Outline

4. Simulation study

5. Application

6. Conclusions

Appendix

References

Four solutions are offered to solve the previous pathologies:

- Changing the settings of the MCMC method
 - ① increasing the number of iterations per chain, with large burn-in and thinning processes
 - ② designing model-specific MCMC algorithms.
- Readjusting the Bayesian model
 - ③ re-write the model in an alternative parametrization (**simple changes**)
 - ④ encode prior information through the prior distributions

However, still no simple rotation/rescaling of the parameter, or the amount of data, allow to visit the posterior distribution properly [3].

Multiple authors showed that changing the **posterior sampling geometries**, i.e. removing the dependence of the parameters on other sampled parameters, **improves** the performance of the MCMC methods [7, 8, 18, 19, 3]

Following Rabe-Hesketh et al. [21, 22], we define the GLLAMM in two parts:

- 1 the response model
- 2 the latent structure

Moreover, **the response model (1)** can be represented by a Generalized Linear Model (GLM) [17, 15] with:

- 1 a distributional
- 2 a systematic part

The response model

Outline

1. Introduction

2. GLLAMM dichotomous

3. Bayesian estimation

4. Simulation study

5. Application

6. Conclusions

Appendix

References

Conditional to all parameters $\mathbf{\Omega} = \{\boldsymbol{\beta}, \boldsymbol{\Lambda}, \boldsymbol{\Theta}, \boldsymbol{\Psi}, \boldsymbol{\Gamma}\}$; and the “stacked” vector of covariates \mathbf{X} and \mathbf{W} ; **the distributional part** is defined by:

$$f(y_{jkd} = 1 \mid \mathbf{X}, \mathbf{W}, \mathbf{\Omega}) = \pi_{jkd}^n (1 - \pi_{jkd})^{1-n} \quad (1)$$

Furthermore, **the systematic part** is defined in the following form:

$$P(y_{jkd} = 1 \mid \mathbf{X}, \mathbf{W}, \mathbf{\Omega}) = \pi_{jkd} = h(\tau_k + v_{jkd}) \quad (2)$$

where τ_k is k 'th item threshold, assumed to be zero for the binary case [21].

The response model (cont.)

Outline

Moreover, the inverse-link function $h(\cdot)$ can be defined in three ways:

$$h(x) = \begin{cases} \exp(x)[1 + \exp(x)]^{-1} \\ \Phi(x) \\ \exp(-\exp(x)) \end{cases} \quad (3)$$

corresponding to the logistic, standard normal $\Phi(x)$, and Gumbel (extreme value type I) cumulative distributions, respectively.

The response model (cont.)

1. Introduction

2. GLLAMM dichotomous

3. Bayesian estimation

4. Simulation study

5. Application

6. Conclusions

Appendix

References

Finally, the linear predictor is defined by:

$$v_{jkd} = \sum_{p=1}^P x_{jp} \beta_p + \sum_{m=2}^{M+1} \sum_{k=1}^{K_{(m)}} \eta_k^{(m)} \alpha_k^{(m)} + \sum_{l=2}^{L+1} \sum_{d=1}^{D_{(l)}} \theta_{jd}^{(l)} \lambda_d^{(l)} \quad (4)$$

Which after the appropriate “stacking”:

$$\begin{aligned} v_{jkd} &= \mathbf{X}_j \boldsymbol{\beta} + \boldsymbol{\eta} \boldsymbol{\alpha} \mathbf{A}_j + \boldsymbol{\theta} \boldsymbol{\lambda} \mathbf{B}_j \\ &= \mathbf{X}_j \boldsymbol{\beta} + \boldsymbol{\Theta} \boldsymbol{\Lambda} \mathbf{H}_j \end{aligned} \quad (5)$$

The latent structure

Outline

1. Introduction

2. GLLAMM dichotomous

3. Bayesian estimation

4. Simulation study

5. Application

6. Conclusions

Appendix

References

The structural model for the latent variables is represented in the following form:

$$\Theta = \underset{(S \times S)}{\Psi} \underset{(S \times 1)}{\Theta} + \underset{(S \times Q)}{\Gamma} \underset{(Q \times 1)}{W} + \underset{(S \times 1)}{\zeta} \quad (6)$$

where $S = K + D$, $K = \sum_m K_m$, and $D = \sum_l D_l$.

Notice equation (6) is the generalization of a single-level Structural Equation Models (SEM) to a multilevel setting.

we could set the restriction $\boldsymbol{\alpha}^{(2)} = -\boldsymbol{\lambda}^{(2)}$ where $\boldsymbol{\lambda}^{(2)} > \mathbf{0}$. In that case we get a multidimensional generalization of the linear predictor observed in the archetypical Rasch [23], or 2PL [14] models, i.e. $\lambda_d^{(2)}(\theta_{jd}^{(2)} - \eta_k^{(2)})$

In addition,

$\boldsymbol{\alpha}^{(3)} = [\alpha_{11}^{(3)}, \dots, \alpha_{15}^{(3)}, \alpha_{21}^{(3)}, \dots, \alpha_{25}^{(3)}, \alpha_{31}^{(3)}, \dots, \alpha_{35}^{(3)}]^T$
 $= [1, \dots, 1]^T$, indicating texts difficulties explain directly the items difficulties at the lower level.

2. GLLAMM dichotomous

3. Bayesian estimation

4. Simulation study

5. Application

6. Conclusions

Appendix

References

Following Skrondal and Rabe-Hesketh [26], the framework has two main assumptions:

- (M1) **Complete latent space.**[11] In the GLLAMM representation, the space is complete if we consider all latent variables Θ at levels $l > 1$ and $m > 1$.
- (M2) **Local Independence.** It assumes independence conditional on all the latent dimensions and covariates, at different hierarchical levels; effectively modeling all the observed dependencies.

Model Assumptions (cont.)

Outline

1. Introduction

2. GLLAMM dichotomous

3. Bayesian estimation

4. Simulation study

5. Application

6. Conclusions

Appendix

References

Local Independence is defined as follows:

$$f(\mathbf{y} = \mathbf{1} \mid \mathbf{X}, \mathbf{W}, \boldsymbol{\Omega}) = \prod_{j=1}^J \prod_{d=1}^D \prod_{k=1}^K f(y_{jkd} = 1 \mid \mathbf{X}, \mathbf{W}, \boldsymbol{\Omega}) \quad (19)$$

Model Assumptions (cont.)

Appendix

References

- It is built on a simulation-based estimation method, therefore, it can handle all kinds of priors and data-generating processes [6].
- While the likelihood for the data and priors for the parameters are used to define the posterior sampling distributions, they can also be used in a generative way [16].
- Because the procedure integrates prior knowledge about the parameters, it can produce results even in scenarios where the Maximum Likelihood methods (ML) have issues of non-convergence or improper estimation [26, 6, 16]

We used the unit variance identification scheme (UVI), that is, to set the scale of the higher-order dimension and sub-dimensions to one:

- $\sigma_{\theta}^{(3)} = 1$
- $\mathbf{S}^{(2)} = \boldsymbol{\sigma}_{\theta}^{(2)} \mathbf{I}$ with $\boldsymbol{\sigma}_{\theta}^{(2)} = [1, 1, 1]^T$
- $\mu_{\eta} = 0, \sigma_{\eta} = 1, \delta_{\eta} = 2$

The first two turned the covariance matrix into a correlation, i.e. $\boldsymbol{\Sigma}^{(2)} = \mathbf{R}^{(2)}$.
